Fiber optic adapter and pigtail connection

Overview

Understand fiber optic pigtails — definition, types, and how they differ from patch cords. Learn why pigtails ensure reliable, low-loss fiber terminations.

Key Takeaways

A fiber optic adapter is not a pigtail; an adapter connects two fiber connectors, while a pigtail has a connector on one end and bare fiber on the other for splicing. What is a Fiber Optic Pigtail? A fiber optic pigtail is a short length of optical fiber with a factory-terminated connector on one end and a bare fiber on the other end designed for splicing into a main fiber cable in the field.

Pigtails are commonly used in optical distribution frames (ODFs), patch panels, or terminal boxes to provide a low-loss, reliable connection between backbone cables and active equipment. They are ideal for single-mode or multimode applications and come with various connector types such as SC, LC, ST, or FC. What is a Fiber Optic Adapter?

A fiber optic adapter (sometimes called a coupler) is a passive device that joins two fiber optic connectors together, allowing light to pass from one fiber to another without splicing. Adapters are used to connect patch cords or pigtails to equipment or to extend fiber runs. Unlike pigtails, adapters do not have bare fiber ends and do not require splicing; they simply provide a stable interface between two connectors.
