

Fiber optic cable melts due to heat

Overview

Higher temperatures tend to increase the attenuation due to alterations in the glass's refractive index.

Key Takeaways

Fiber optic cables do not have a single melting point; the core glass can withstand extremely high temperatures, but the coatings and buffer materials fail at much lower temperatures, typically between 70°C and 900°F (482°C) depending on the type. Core Material vs Coatings Silica glass fibers (SiO_2), the most common core material, have very high heat tolerance and can theoretically withstand temperatures above 1000°C. However, the polymer coatings, buffer tubes, and adhesives used in cable construction degrade at much lower temperatures, limiting practical operating temperatures to around 70°C for standard cables and up to 315°C for high-temperature designs using specialized epoxies or ceramic bonding agents.

Borosilicate glass fibers can be used in high-temperature applications up to 900°F (482°C) if special assembly techniques are applied, such as epoxy-less or ceramic-based bonding. Plastic optical fibers (PMMA) have a much lower melting point, around 70°C (158°F), which is the maximum exposure temperature for these fibers.

Practical Operating Limits

Standard fiber optic cables are rated for continuous operation between -40°C and 70°C, with some specialized industrial fibers capable of withstanding up to 125°C or higher. Exceeding these temperatures can cause softening, deformation, or failure of the coatings and buffer materials, even if the glass core remains intact. In extreme industrial environments, high-temperature fibers with polyimide or metal coatings are required to maintain performance above 200°C.

Summary

While the glass core itself melts at very high temperatures, the limiting factor for fiber optic cables is the surrounding polymer coatings, adhesives, and buffer materials, which fail at much lower temperatures. For standard silica fibers, practical melting or failure of the cable occurs around 70°C, whereas specialized high-temperature fibers can operate up to 315–482°C depending on construction and materials used.
