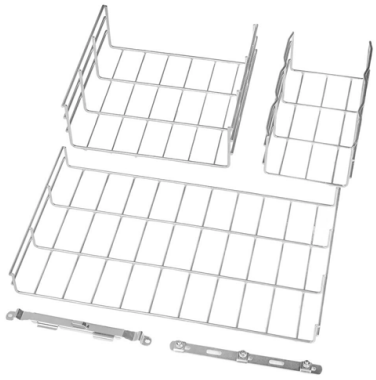
Grounding Standards for Household Electrical Distribution Boxes



Overview

Master the requirements for bonding devices and ensuring the unbroken safety path of the grounding conductor within all electrical boxes.

Key Takeaways

Home electrical distribution boxes must be properly grounded and bonded according to NEC Article 250 to ensure safety, prevent electrical shock, and allow overcurrent devices to operate effectively.

Key Grounding Principles

Grounding provides a low-impedance path for fault currents to safely dissipate into the earth, protecting both people and equipment from electrical hazards, including surges and lightning strikes. Bonding ensures that all metallic, non-current-carrying components are electrically connected, maintaining the same potential and preventing dangerous voltage differences.

NEC Requirements

Article 250 of the NEC governs grounding and bonding for residential electrical systems. Grounding electrodes (e.g., rods, plates, or building steel) must be connected to the neutral at the service entrance. Equipment grounding conductors must run with each feeder and branch circuit, sized according to NEC Table 250.

122, and connected to the panel ground bus. Bonding jumpers are required across expansion or deflection fittings in conduits to maintain electrical continuity. Metal enclosures for panels, pull boxes, and switchgear must have bolted ground connectors and be bonded to incoming and outgoing conduits.

Practical Installation Guidelines

Panelboards: Connect the ground conductor from the feeder to the panel's ground bus. All metallic enclosures must be bonded to this bus. Pull Boxes: Install bolted ground connectors and connect to grounding bushings on all conduits with a copper conductor for boxes containing power feeders.

Conduits: Use conduit grounding bushings and bond all metal raceways and boxes into a continuous system. Equipment Grounding Conductors: Use conductors equal in size to phase conductors for sensitive equipment to reduce impedance and improve fault clearing times. Metal Piping and Raised Floors: Bond all metal piping to the service equipment ground bus and connect raised floor systems to building steel with appropriate conductors.

Testing and Safety

Maximum resistance to earth should not exceed 25 ohms for effective grounding. Regular testing ensures the grounding system remains effective and can safely carry fault currents. Proper grounding and bonding prevent electrical shock, equipment damage, and voltage instability.

By following these NEC-based guidelines and best practices, home electrical distribution boxes can be safely grounded and bonded, ensuring both compliance and protection for occupants and equipment.
