Power distribution box grounding

Overview

Each DISTRIBUTION BOX and controller must be grounded. On the US market, a 5.26 mm 2 (10 AWG) ground wire must be used, and in all other markets a 6 mm 2 must be used.

Key Takeaways

A power distribution box must be properly grounded to ensure safety, protect equipment, and comply with electrical standards.

Importance of Grounding

Grounding a distribution box is essential for several reasons: it protects personnel from electric shock, channels fault currents safely into the earth, prevents equipment damage from lightning or transient overvoltages, and stabilizes system voltage to ensure reliable operation of protective devices like circuit breakers and relays. Poor grounding can lead to electrical leakage, short circuits, or even electric shock accidents.

Grounding the Box Body

For metal distribution boxes, grounding involves connecting a ground wire from the box to a central grounding point.

In the U

S, a 10 AWG (5. 26 mm^2) wire is typically used, while in other markets a 6 mm^2 wire is standard. The connection is usually made via threaded studs at the bottom of the housing to a mounting plate, which is then connected to the factory central ground.

The total ground resistance between system parts should be less than 0. 1 Ohm to ensure safety.

Grounding the Door

Even if the box body is grounded, metal doors must also be bonded to ground. This prevents static discharge and ensures that any accidental contact with live wires does not create a shock hazard.

NE

C 250. 148 mandates that all metallic parts, including cabinet doors, must be bonded to ground using a designated grounding screw or clip.

Grounding Methods

Direct Ground Wire: Connect the box or door to a ground rod or central grounding point. Ensure a large contact area for effective grounding. Parallel Grounding for Multiple Spindles: If multiple spindles or components are connected, ground wires can be run in parallel to reduce total resistance.

For example, a 60 m tool cable with a 16 mm^2 ground wire can achieve a total resistance well below 100 mOhm. Ground Rod Installation: Ground rods should be buried underground, and their resistance tested with a voltmeter. If resistance is too high, additional rods or relocation may be necessary.

Testing and Verification

After installation, use a voltmeter to measure the grounding effectiveness. A properly grounded box will show a voltage below safe limits, confirming that the grounding system is effective. Regular inspection and maintenance are recommended to ensure connections remain secure and corrosion-free.

Summary

Proper grounding of a power distribution box involves: Connecting the box body to a central ground using appropriately sized wire. Bonding all metallic doors and panels to the same ground. Ensuring total ground resistance is below 0.

1 Ohm. Testing and maintaining the grounding system regularly to ensure safety and compliance with standards.
