Storage links require a fiber optic switch

Overview

When a server or host computer needs to access a storage device, the FC switch directs the request to the appropriate storage device.

Key Takeaways

Connecting storage to a Fibre Channel switch involves using FC ports on both storage devices and switches, configuring zoning, and ensuring proper SAN topology for high-speed, lossless data transfer.

Fibre Channel Overview

Fibre Channel (FC) is a high-speed network protocol primarily used to connect storage devices to servers in a Storage Area Network (SAN) using optical fiber or copper cabling. It supports data rates from 1 Gbps up to 128 Gbps and provides lossless, in-order delivery of block data for storage workloads, including SCSI and NVMe commands.

F

C networks typically form a switched fabric, where multiple FC switches interconnect to provide scalable and redundant paths.

Key Components for Storage Connectivity

Host Bus Adapters (HBAs): Installed in servers, HBAs provide the interface to the FC SAN and handle the encapsulation of SCSI or NVMe commands into FC frames.

C Switches: Devices like the Cisco MDS 9124V or 9148T provide multiple FC ports for connecting storage arrays and servers. These switches support features such as automatic zoning, nonblocking forwarding, and link-level encryption. Storage Arrays: Disk arrays or all-flash arrays connect to the FC switch via N_Ports, which are node ports on the storage device.

Port Types and TopologyN_Port (Node Port): Port on a storage device or server HBA that connects to an FC switch. F_Port (Fabric Port): Port on the FC switch that connects to an N_Port, forming a point-to-point connection.

IS

L (Inter-Switch Link): High-speed multi-lane connections between switches for core or non-edge connectivity.

SA

Ns often use dual-fabric topology for redundancy, where two independent fabrics connect to the same storage and hosts, ensuring continuous connectivity if one fabric fails.

Configuration Considerations

Zoning: Defines which HBAs can access which storage ports, isolating traffic and improving security. Zones can be configured per host or per application. NVMe/FC Support: Modern FC switches support NVMe over Fibre Channel, allowing high-performance flash storage to be used without hardware upgrades.

Redundancy and Performance: Use multiple paths from hosts to storage arrays, leveraging multipathing software to balance load and provide failover.

Practical Steps for Connecting Storage

Install HB

As in the host servers and connect them to the FC switch using fiber optic cables. Connect storage array N_Ports to F_Ports on the switch. Configure zoning on the switch to allow the host HBAs to access the intended storage ports.

Verify connectivity using switch management tools and SAN analytics features. Optionally, configure multipathing on the host to utilize multiple paths for redundancy and performance. By following these steps and using proper FC switch features, storage devices can achieve high-speed, reliable, and secure connectivity in a SAN environment.
